ARTICLE INFO

Keywords: Unconstrained optimization; Descent property; Conjugacy condition; Global convergence; Conjugate gradient algorithm.

ABSTRACT

Some problems have no analytical solution or too difficult to solve by scientists, engineers, and mathematicians, so the development of numerical methods to obtain approximate solutions became necessary. Gradient methods are more efficient when the function to be minimized continuously in its first derivative. Therefore, this article presents a new hybrid Conjugate Gradient (CG) method to solve unconstrained optimization problems. The method requires the first-order derivatives but overcomes the steepest descent method’s shortcoming of slow convergence and needs not to save or compute the second-order derivatives needed by the Newton method. The CG update parameter is suggested from the Dai-Liao conjugacy condition as a convex combination of Hestenes-Stiefel and Fletcher-Revees algorithms by employing an optimal modulating choice parameter \( \tau \) to avoid matrix storage. Numerical computation adopts an inexact line search to obtain the step-size that generates a decent property, showing that the algorithm is robust and efficient. The scheme converges globally under Wolfe line search, and it’s like is suitable in compressive sensing problems and M-tensor systems.

1. Introduction

Conjugate Gradient (CG) method was initially proposed for solving linear systems and unconstrained minimization. The method is an excellent choice for solving optimization problems by scientists, engineers, and mathematicians. The method has the following form

\[
\min f(x),
\]

\( x \in \mathbb{R}^n \)

where \( f: \mathbb{R}^n \rightarrow \mathbb{R} \) is a smooth nonlinear function.

The iterative scheme of the method is computed by

\[
 x_{k+1} = x_k + \alpha_k d_k,
\]

\( x_0 \in \mathbb{R}^n \)
in which $\alpha_k > 0$ is a step length obtained by a suitable exact or inexact line search. However, $\alpha_k$ is usually generated by an inexact line search, such as the standard Wolfe line search

$$f(x_k + \alpha_k d_k) \leq f(x_k) + \delta \alpha_k g_k^T d_k,$$

(3)

$$g(x_k + \alpha_k d_k)^T d_k \geq \sigma g_k^T d_k.$$  

(4)

Or using strong Wolfe condition, which consists of (3) and

$$|g(x_k + \alpha_k d_k)^T d_k| \leq -\sigma g_k^T d_k$$

(5)

where $0 < \delta < \sigma < 1$ and $d_k$ is the search direction given by

$$d_{k+1} = -g_{k+1} + \beta_k d_k,$$

(6)

where $\beta_k$ is a scalar called CG (update) parameter (Babaie-Kafaki, 2011).

Liu & Du (2019) proposed a CG method by transforming $M$-tensor system to general unconstrained minimization problem and solving a kind of nonsmooth optimization problems with $l_1$-norm, the given numerical experiments show the efficiency of the suggested method due to simplicity, low storage and nice convergence properties of the CG methods. Esmaeili, Rostami & Kimiaeı (2018) employed a new CG method to solve compressive sensing problems that play an important role in medical and astronomical imaging, file restoration, image, video coding, etc. applications. The method is characterized by $l_0$-minimization that is NP-hard in general. Hence, replaced the $l_0$-Norm by the closest convex norm, which is the $l_1$-norm leads to the minimization problem. Similarly, Guo & Wan (2019) developed a CG algorithm to solve an engineering problem originated from compressed sensing of sparse signals. Numerical tests and preliminary application in recovering sparse signals indicate that the established algorithm outperforms similar algorithms in the literature, especially for solving large-scale problems and singular ones. It was shown that the compressed sensing of sparse signals does not involve computing the Jacobian matrix or its approximation, both information storage and computational cost of the algorithm are lower. Recently, Liu, Du & Chen (2020) suggested a kind of important tensor optimization problem with higher-order nonlinear equations, widely used in engineering and economics. The algorithm is concerned with solving $M$-tensor equations by transforming the equations to nonlinear unconstrained optimization problems. The effectiveness of the proposed nonlinear conjugate gradient method was compared with the three-term conjugate gradient method and Newton method. Numerical results show that the proposed nonlinear conjugate gradient method is potentially efficient.

Different values of the scalar parameters $\beta_k$ correspond to several CG schemes. Some excellent CG algorithms employed in practice to obtain new formulas include: Hestenes & Stiefel (HS) (1952), Polak, Ribiere & Polyak (PRP) (1967), Liu & Storey (LS) (1991), Fletcher & Reeves (FR) (1964), Fletcher (Conjugate Descent (CD)) (1987), and Dai & Yuan (1991) schemes. Let $\| \|$ denotes Euclidean norm and define $s_k = x_{k+1} - x_k$ and $y_k = g_{k+1} - g_k$ (Dai & Yuan, 2001). Numerical experiments show that the FR, DY and CD conjugate schemes are characterized by strong global convergence properties and have poor practical performances due to jamming. On the contrast, LS, HS and PRP have better
practical performances, but may not always be convergent (Babaie-Kafaki & Ghanbari, 2014c). To improve these schemes’ behavior and avoid numerical uncertainty, researchers were interested in combining CG schemes of the two groups (Babaie-Kafaki & Mahdavi-Amiri, 2013).

There are some strengths and weaknesses in the theory of CG schemes. The first global convergent property of FR method with exalt line was proved by Zoutendijk (1970); where Al-Baali (1985) extended this result to an inexact line search and show that the method generates sufficient descent direction under the strong Wolfe conditions using the constraint $\sigma < \frac{1}{2}$. However, the HS and PRP schemes possess an automatic approximate restart feature that addresses a jamming problem that makes them numerically efficient (Babaie-Kafaki, 2013). Here this research considers a new convex combination of HS and FR conjugate gradient methods. The corresponding conjugate gradient parameters are

$$\beta_k^{HS} = \frac{g_k^T y_k}{d_k^T y_k},$$

$$\beta_k^{FR} = \frac{\|g_{k+1}\|^2}{\|g_k\|^2}$$

(7) and

(8)

The structures of CG update parameters were obtained from conjugacy condition and secant equation which depends on the exact line search. These procedures require computation and storage of the Hessian matrix, respectively. However, the practical numerical analysis adopts inexact line searches instead of exact line searches to obtain the step-size. To address these drawbacks, this article, therefore, presents a hybrid method from Dai-Liao conjugacy condition so that, if the modulating parameter $t = 1$, then it reduces to a method that uses pure conjugacy condition. The numerical performance of the Dai-Liao CG method depends on the parameter $t$. The best choice of $t$ remains subject of consideration (Babaie-Kafaki & Ghanbari, 2017).

The article aims to modify the CG methods using classical HS and FR method by employing optimal choice of the parameter $t$ for solving large scale unconstrained optimization problems. This paper is organized as follows: Section 2 presents the proposed method. Convergence results are presented in Section 3. Some numerical results are reported in Section 4. Finally, conclusions are made in Section 5.

2. Literature Review

A large number of hybrid conjugate gradient techniques were proposed. The idea is to combine different conjugate algorithms to use the projection to form a new hybrid convex-combination algorithm to avoid jamming and improve the convergence analysis (Mohammed, et al., 2020). Djordjevic (2016; 2017; 2018) proposed hybrid conjugate gradient algorithms. The conjugate gradient parameters $\beta_k$ are computed as a convex combination of the hybrid parameter $\theta_k$, where they are computed in such a way that the conjugacy condition(s) are satisfied using strong Wolfe line search conditions, which has the following formulas for $\beta_k$ respectively

$$\beta_k^{hyb} = (1 - \theta_k) \beta_k^{PRP} + \theta_k \beta_k^{FR}.$$  (9)
\[ \beta_k^{hyb} = (1 - \theta_k) \beta_k^{LS} + \theta_k \beta_k^{CD}. \]  
(10)

\[ \beta_k^{hyb} = (1 - \theta_k) \beta_k^{HS} + \theta_k \beta_k^{FR}. \]  
(11)

On the other hand; Djordjevic (2019), Al-Namat & Al-Naemi (2020) and Salihu et al. (2020) recently derived new hybrid schemes for solving large scale unconstrained optimization algorithms. The hybrid schemes satisfy the sufficient descent condition in such a way that Newton directions are employed, global convergence analysis were proved under the same conditions above, and the algorithms are characterized by following \( \beta_k \).

\[ \beta_k^{hyb} = (1 - \theta_k) \beta_k^{LS} + \theta_k \beta_k^{FR}. \]  
(12)

\[ \beta_k^{CLCS} = (1 - \theta_k) \beta_k^{LS} + \theta_k \beta_k^{CD}. \]  
(13)

\[ \beta_k^{FG} = (1 - \theta_k) \beta_k^{MMWU} + \theta_k \beta_k^{RMAR}. \]  
(14)

Numerical comparisons show that these algorithms behave better than some known methods. Based on the modified BFGS method proposed by Li & Fukushima (2001), Lotfi & Hosseini (2019) presented a new value of the parameter \( t \) in Dai-Liao CG scheme. The proposed method's global convergence property was established, and numerical results illustrated the computational efficiency of the new method. Considerable efforts have recently been made to extend CG methods to solve monotone nonlinear equations, Abubakar et-al. (2019) presented a modification of the FR CG method for constrained monotone nonlinear equations. The method possesses sufficient descent property, and its global convergence was proved. Numerical experiments show efficiency of the proposed method using some benchmark test problems while applying the method in signal and image recovery problems arising from compressive sensing. Also, Xue et-al. (2018) suggested DY CG method for solving large-scale unconstrained optimization problems, which possesses a spectral CG parameter in which the search direction generated at each iteration is independent of any line search. Global convergence of the method is also established using strong Wolfe conditions. Finally, comparison experiments on impulse noise removal are reported and demonstrated the effectiveness of the method.

These new methods are based on secant equations or conjugacy condition, for nonlinear conjugate gradient methods, the conjugacy condition is given by

\[ d_{k+1}^T y_k = 0. \]  
(15)

Perry (1978) extended the result in (15) by exploiting the following secant condition of quasi-Newton scheme \( B_{k+1} s_k = y_k \) and quasi-Newton search direction given by \( B_{k+1} d_{k+1} = -g_{k+1} \), where \( B_{k+1} \) is a square matrix of the Hessian approximation; as

\[ d_{k+1}^T y_k = -g_{k+1}^T s_k, \]  
(16)
which implies that (16) holds for exact line search, where \(-g_{k+1}^Ts_k = 0\), but practical numerical computations normally adopt inexact line search; that is, \(-g_{k+1}^Ts_k \neq 0\). For this reason, Dai and Liao (2001) replaces (16) with a condition called extended conjugacy condition:

\[
d_{k+1}^Ty_k = -tg_{k+1}s_k, \text{ where } t \geq 0. \tag{17}
\]

Due to the simpler structure and low memory requirements of Dai-Liao conjugate gradient methods, Yao et al. (2019) combined Dai-Liao conjugacy condition with a modified symmetric Perry matrix to propose a class of three-term Dai-Liao conjugate gradient algorithms. The method possesses both Dai-Liao conjugacy conditions and sufficient descent conditions. Meanwhile, the global convergence is established under Wolfe line search for general objective functions. Numerical experiments show that the proposed method is promising. The best choice of \(t\) remains subject of consideration, with several optimal choices for the parameter proposed in (Babaie-Kafaki, 2015; Babaie-Kafaki & Ghanbari, 2014a; Babaie-Kafaki & Ghanbari, 2014b; Babaie-Kafaki & Ghanbari, 2015; Babaie-Kafaki & Ghanbari, 2017; Waziri, Ahmed & Sabi’u, 2019). Motivated by the above, this research proposes a hybrid parameter by employing the choice of the parameter \(t\) in Andrei (2017) using (17) to access and combine the CG update parameters’ strength.

### 3. Research Methodology

In this section, this research combines the CG update parameters proposed by Hestenes & Stiefel (1952) with Fletcher & Reeves (1964) conjugate descent based on Dai-Liao conjugacy condition as a convex combination as follows:

\[
\beta_k^{\text{DHF}} = (1 - \theta_k) \beta_k^{\text{HS}} + \theta_k \beta_k^{\text{FR}}. \tag{18}
\]

From relations (7) and (8), it obtains

\[
\beta_k^{\text{DHF}} = (1 - \theta_k) \left( \frac{g_{k+1}^Ty_k}{d_k^Ty_k} \right) + \theta_k \left( \frac{\|g_{k+1}\|^2}{\|g_k\|^2} \right), \tag{19}
\]

where \(\theta_k\) is the hybridization scalar parameter satisfying \(\theta_k \in [0,1]\). It is obvious that if \(\theta_k \leq 0\), set \(\theta_k = 0\), then \(\beta_k^{\text{DHF}} = \beta_k^{\text{HS}}\) and if \(\theta_k \geq 0\), set \(\theta_k = 1\), then \(\beta_k^{\text{DHF}} = \beta_k^{\text{FR}}\). On the other hand, if \(0 < \theta_k < 1\), then \(\beta_k^{\text{DHF}}\) is a proper convex combination of \(\beta_k^{\text{HS}}\) and \(\beta_k^{\text{FR}}\). Therefore, from relation (6) and by taking the inner product with the vector \(y_k^T\) it obtains

\[
d_{k+1} = -g_{k+1} + \left(1 - \theta_k\right) \left( \frac{g_{k+1}^Ty_k}{d_k^Ty_k} \right) + \theta_k \left( \frac{\|g_{k+1}\|^2}{\|g_k\|^2} \right) s_k, \tag{20}
\]

\[
d_{k+1}^Ty_k = -g_{k+1}^Ty_k + \left(1 - \theta_k\right) \left( \frac{g_{k+1}^Ty_k}{d_k^Ty_k} \right) + \theta_k \left( \frac{\|g_{k+1}\|^2}{\|g_k\|^2} \right) s_k^Ty_k. \tag{21}
\]

Applying \(y_k^T\) on \(d_{k+1} = -\nabla^2 f(x_{k+1})^{-1} g_{k+1}\) and equating with (21), lead to the following hybridization parameter of Djordjevic (2018), which imply that \(d_{k+1}\) satisfies Newton direction:
\[
\theta_k = \frac{(-s_k^T g_{k+1}) \|g_k\|^2}{(y_k^T s_k) \|g_{k+1}\|^2 - (s_k^T y_k) \|g_k\|^2}
\] (22)

Here, this research uses Dai-Liao conjugacy condition (17) on (21), and after some algebra, this research proposes another hybridization parameter as follows:

\[
\theta_k = \frac{(-s_k^T g_{k+1}) \|g_k\|^2}{(y_k^T s_k) \|g_{k+1}\|^2 - (s_k^T y_k) \|g_k\|^2}
\] (23)

However, for large-scale problems, the update parameter choices that do not require evaluation of the Hessian matrix are often required. Therefore, to have an algorithm for solving large-scale problems, this research computes the modulating parameter \( t^* \) from optimal choice obtain in Babaie-Kafaki and Ghanbari (2015) and Andrei (2017).

\[
t^* = \frac{s_k^T y_k}{s_k^T s_k}.
\] (24)

3.1 Dai-Liao Hybrid Hestenes-Stiefel and Fletcher-Reeves (DHF) Algorithm

Step 1. Initialization. Select \( x_0 \in \mathbb{R}^n, \varepsilon > 0 \) and parameter \( 0 < \delta < \sigma < 1 \). Compute \( f(x_0) \) and \( g_0 \).

Step 2. Test for Continuation of Iterations. If \( \|g_k\| \leq \varepsilon \), then stop.

Step 3. Line Search. Compute \( \alpha_k > 0 \) satisfying Wolfe conditions (3) and (5).

Step 4. Computation of \( \theta_k \). If \( (y_k^T s_k) \|g_{k+1}\|^2 - (s_k^T y_k) \|g_k\|^2 = 0 \), then set \( \theta_k = 0 \); otherwise, Compute \( \theta_k \) by (23) and (24).

Step 5. Computation of \( \beta_k^{DHF} \). If \( 0 < \theta_k < 1 \), then compute \( \beta_k^{DHF} \) by (19).

Step 6. Computation of Search Direction. Compute \( d = -g_{k+1} + \beta_k^{DHF} s_k \). If restart criterion of Powell \( \left| g_{k+1}^T g_k \right| > c \|g_{k+1}\|^2 \), then set \( d_{k+1} = -g_{k+1} \); otherwise, define \( d_{k+1} = d \). Compute \( \alpha_k \), set \( k = k + 1 \) and go to step 2.

3.2 Convergence Analysis

In this section, the convergence result of the hybrid CG method is analyzed based on strong Wolfe condition, an algorithm has to possess both sufficient descent condition and global convergence properties to be convergent.

3.2.1. Sufficient Descent Condition

Definition: Search direction satisfies descent directions (or equivalently, satisfy the decent condition) if an only if

\[
\text{Salihu et al. 38}
\]
\[ d_k^T g_k < 0, \]  
(26)

and also satisfies sufficient descent condition if and only if

\[ d_k^T g_k \leq -c \|g_k\|^2, \forall k \geq 0, \]  
(27)

where c is positive constant.

Theorem 3.1. Consider a CG method with search direction (6) and \( \beta_k^{DHF} \) generated by (19), then condition (27) holds.

Proof: From DHF algorithm, suppose the restart criterion of Powell (1984) condition (25) holds, then \( d_k = -g_k \) and (27) holds. So, this research assumes that (25) does not hold. Then this research has

\[ |g_{k+1}^T g_k| \leq c\|g_{k+1}\|^2, \]  
(28)

If \( k = 0 \), it to see that it holds; \( d_0 = -g_0 \), so \( g_0^T d_0 = -\|g_k\|^2 \), then it can be concluded that (25) holds for \( k = 0 \). Next is to show that it holds for \( k > 0 \).

By taking the inner product of (6) with vector \( g_k^T \) this research has

\[ d_{k+1}^T g_{k+1} = -\|g_{k+1}\|^2 + \beta_k d_k^T g_{k+1}. \]  
(29)

Firstly, suppose that \( \theta_k \leq 0 \), then \( \beta_k = \beta_k^{HS} \), it follows from (7) and (29) with triangular inequality that

\[ d_{k+1}^T g_{k+1} \leq -\|g_{k+1}\|^2 + \left| d_k^T g_{k+1} \right| \left| g_{k+1}^T y_k \right|. \]

From (5), this research has

\[ |d_k^T g_{k+1}| \leq -\sigma d_k^T g_k \]  
(30)

\[ d_k^T y_k = d_k^T g_{k+1} - d_k^T g_k \leq -\sigma d_k^T g_k - d_k^T g_k \]

\[ \geq -(1 - \sigma) d_k^T g_k \geq 0 \]  
(31)

Using relations (30) and (31) with the above inequality, it obtains

\[ d_{k+1}^T g_{k+1} \leq -\|g_{k+1}\|^2 + \frac{(-\sigma) d_k^T g_k}{-(1 - \sigma) d_k^T g_k} \left| g_{k+1}^T y_k \right|, \]

But from (28) and \( y_k = g_{k+1} - g_k \) it holds \( g_{k+1}^T y_k \leq \|g_{k+1}\|^2 + \|g_k^T g_k\| \leq 1.2\|g_{k+1}\|^2 \), so that we have
\[
- \|g_{k+1}\|^2 + \frac{1.2}{1-\sigma} \|g_{k+1}\|^2 \\
\leq - \left(1 - \frac{1.2}{1-\sigma}\right) \|g_{k+1}\|^2 \leq - \left(1 - \frac{2.2}{1-\sigma}\right) \|g_{k+1}\|^2.
\]

Denote \(c_1 = \left(\frac{1-2.2}{1-\sigma}\right)\), so that this research has

\[
d_d^T g_{k+1} \leq -c_1 \|g_{k+1}\|^2.
\]

Secondly, suppose that \(\theta_k \geq 1\), then \(\beta_k = \beta_k^{FR}\), it follows from (8) and (29) with triangular inequality that

\[
d_d^T g_{k+1} \leq -\|g_{k+1}\|^2 + \frac{\|g_{k+1}\|^2}{\|g_k\|^2} |g_{k+1}^T d_k|.
\]

Let remind the fact that (27) holds for FR method in the presence of (3) and (5) was initially mentioned in (Hager & Zhang, 2006) and later in (Djordjevic; 2018; 2019).

So, there exists a constant \(c_2 > 0\), such that

\[
d_d^T g_{k+1} \leq -c_2 \|g_{k+1}\|^2
\]

Finally, if \(\theta_k \in (0,1)\), then \(0 < a_1 < \theta_k < a_2 < 1\). Therefore, from (14) and (20) it can write

\[
d_d^T g_{k+1} = \theta_k g_{k+1}^T g_{FR}^{k+1} + (1 - \theta_k) g_{k+1}^T g_{HS}^{k+1},
\]

which implies that

\[
g_{k+1}^T d_{FR}^{k+1} = a_1 g_{k+1}^T d_{FR}^{k+1} + (1 - a_1) g_{k+1}^T d_{HS}^{k+1}.
\]

Denote \(c = a_1 c_2 + (1 - a_2) a_1\). Then finally, we get

\[
d_d^T g_{k+1} \leq -c \|g_{k+1}\|^2.
\]

### 3.3. Convergence Analysis

In this section, this research applies the following theorems to illustrate the global convergence of DHF method. It is necessary to show that \(\theta_k\) and \(t^*\) are bounded. Therefore, the following basic assumptions are:

Assumption (i). The level set \(S = \{x \in \mathbb{R} : f(x) \leq f(x_0)\}\), is bounded from below. That is, there exists a positive constant \(B\) such that \(\|x\| \leq B, \forall x \in S\).

Assumption (ii). In a neighborhood \(N\) of \(S\), the objective function \(f\) is continuously differentiable and its gradient \(g(x)\) is Lipschitz continuous on \(N\) that is, there exist a constant \(L > 0\) such that
\[ \|f(x) - f(y)\| \leq L\|x - y\|, \text{ for all } x, y \in N. \] (35)

Under Assumptions (i) and (ii) on \( f \), there exist a constant \( \Gamma \) such that
\[ \|g(x)\| \leq \Gamma, \text{ for all } x \in S. \] (36)

For any conjugate gradient method with a strong Wolfe line search, the convergence holds. But, for general function, only a weak form of the Zoutendijk condition is needed (Dai & Liao, 2001).

Lemma 3.1. Let Assumptions (i) and (ii) hold. Consider the methods (2) and (6), where \( d_k \) is a descent direction and \( \alpha_k \) satisfies (3) and (5). If
\[ \sum_{k=1}^{\infty} \frac{1}{\|d_k\|^2} = \infty, \] (37)
then
\[ \lim_{k \to \infty} \inf \|g_k\| = 0. \] (38)

A CG method converges globally if \( g_k = 0 \) for some \( k \) or (38) holds.

Theorem 3.2. Consider the iterative method, defined by DHF method. Let \( d_{k+1} \) be a descent direction, then either \( g_k = 0 \), for some \( k \), or
\[ \lim_{k \to \infty} \inf \|g_k\| = 0. \] (39)

The proof is using contradiction, that theorem (3.1) is not true.

Proof: Let \( g_k \neq 0 \), for all \( k \). Then it has to prove (39). Suppose, on the contrary, that (39) does not hold, which means the gradient is bounded away from zero. Then there exists a constant \( r > 0 \), such that
\[ \|g_k\| \geq r. \] (40)

Let \( D \) be the diameter of the level set \( S \), then
\[ \|s_k\| \leq D. \] (41)

Because the descent condition holds for DHF method. Since it has \( d_{k+1} \neq 0 \), it is sufficient to prove that \( d_{k+1} \) is bounded above, so from relation (20), it has
\[ \|d_{k+1}\| = \|g_{k+1} + |1 - \theta_k| \cdot |\beta_k^H S| + |\theta_k| \cdot |\beta_k^{FR}| \cdot d_k\|. \] (42)

Salihu et al. 41
But it holds from (27), (28), (31), (36), (40), and (41) that

\[
|\beta_{HS}^k| = \left| \frac{g_{k+1}^Ty_k}{d_k^Ty_k} \right| \leq \frac{\|g_{k+1}\|\|y_k\|}{d_k^Ty_k} \leq \frac{rL\|s_k\|}{c(1-\sigma)\|g_k\|^2} \leq \frac{rLD}{c(1-\sigma)r^2} \quad \text{(43)}
\]

\[
|\beta_{FR}^k| = \frac{\|g_{k+1}\|^2}{\|g_k\|^2} \leq \frac{r^2}{r^2}. \quad \text{(44)}
\]

Applying Lipschitz condition \(\|y_k\| \leq L\|s_k\|\) and (24) implies that

\[
|t| = \left| \frac{s_k^Ty_k}{s_k^Ts_k} \right| \leq \frac{\|s_k\|\|y_k\|}{\|s_k\|^2} \leq \frac{L\|s_k\|^2}{\|s_k\|^2} \leq L. \quad \text{(45)}
\]

It shows that \(\theta_k\) is bounded using (23), so that

\[
|\theta_k| = \left| \frac{(-t s_k^Tg_{k+1})\|g_k\|^2}{(y_k^Ts_k)\|g_{k+1}\|^2 - (g_{k+1}^Ty_k)\|g_k\|^2} \right|
\]

Since

\[
|s_k^Tg_{k+1}| \leq |g_{k+1}^Ty_k| + L\|s\|^2, \quad |s_k^Tg_{k+1}| \leq \|g_{k+1}\|\|s_k\|, \quad g_{k+1}^Ty_k = y_k^Td_k \quad \text{and} \quad g_{k+1}^Ty_k \leq (1-0.2)\|g_{k+1}\|^2,
\]

clearly, it gets

\[
|\theta_k| \leq \frac{t [\|g_{k+1}\|\|s_k\| + L\|s\|^2].r^2}{[c(1-\sigma)\|g_{k+1}\|^2. r^2 + (1-0.2).\|g_{k+1}\|^2. r^2]}
\]

\[
\leq \frac{t [rD + LD^2].r^2}{[c(1-\sigma)\Gamma^2 + (1-0.2)\Gamma^2].r^2},
\]

\[
\leq \frac{t [rD + LD^2]}{\Gamma^2[c(1-\sigma) + (0.8)]},
\]

using (45) implies

\[
\leq \frac{LD[r + LD]}{\Gamma^2[c(1-\sigma) + (0.8)]}
\]

\[
|\theta_k| \leq A. \quad \text{(46)}
\]

Finally, from (42), using (43), (44), and (45), it gets as follows

\[
\|d_{k+1}\| \leq \|g_{k+1}\| + \left[ |1 - \theta_k| \right] \cdot \left[ |\beta_{HS}^k| + |\beta_{FR}^k| \right] \cdot \|d_k\|
\]

\[
\leq \Gamma + \left[ |1 - A| \right] \cdot \frac{rLD}{c(1-\sigma)r^2} + A \cdot \frac{r^2}{r^2} \cdot E.
\]
\[ \leq \Gamma + EF \]
\[ \|d_{k+1}\| \leq \Gamma + EF. \]  
(47)

Therefore, from
\[ \sum_{k \geq 1} \frac{1}{\|d_k\|^2} = \infty. \]

Applying Lemma 3.1, this research concludes that
\[ \lim_{k \to \infty} \inf \|g_k\| = 0. \]

This is a contradiction of (38), so it has been proved (39).

4. Results and Discussion

In this section, we present computational performance of DHF method and compare with Hybrid Hestenes-Stiefel and Fletcher-Revees (HHSFR) of Djordjevic (2018) method. To implement the hybridize CG parameters, the codes were written in Matlab 9.2 (R2018a) and run on a personal computer 2.20 GHz CPU processor and 3.0 GB RAM memory. The test problems are the unconstrained problems from (Andrei, 2008) and (Gould, Orban & Toint, 2003). Since CG schemes are mainly designed to solve large-scale unconstrained optimization, we select 24 unconstrained optimization problems and tested them on a gradually increasing number of dimension(s) from 100 to 1000000 as shown in Table 1. The stopping criterion is set to \( \|g_k\|_\infty \leq 10^{-4} \). Numerical results were compared based on the performance profile of Dolan and Mor’e (2002) and shown graphically in figures 1-2.

Benchmark results are generated by running a solver on a set of problems and recording information of interest such as the number of iterations and the computing time. A solver has higher efficiency when its value of \( P_s(t) \) is higher. The \( P_s(t) \) from the performance, the profile is the fraction of the problem with a high ratio performance \( t \). In a set of problem \( P \) and a set of optimization solver \( S \), a performance comparison of problem \( p \in P \) by a particular algorithm \( s \in S \) is measured. Let, \( t_{p,s} \) be the number of iterations or CPU time required when solving a problem \( p \in P \) with solver \( s \in S \). The performance ratio is defined by \( r_{p,s} = \frac{t_{p,s}}{\min(t_{p,s} \in S)} \). From this expression, it is assumed that \( r_{p,s} \in [1, r_M] \), where \( r_M \geq r_{p,s} \) and \( r_{p,s} = r_M \) only when problem \( P \) is not solved by the solver. Then, graphically, a graph of \( P_s(t) \) versus \( t \in [1, r_M] \) is plotted. In a graph of performance profile, the smallest performance ratio is 1, and it will be located at the most left of \( t \)-axis hence, the top curve represents the most efficient method. In particular, if the set of problems \( P \) is suitably large and representative of problems that are likely to occur in applications, then solver with large probability \( P_s(t) \) are to be preferred.
Figures 1 and Figure 2 show the hybrid coefficients’ performance based on the number of iteration and central processing time per unit. The top left curved indicated fraction or percentage of how fast the coefficient converges, while the top right determines the fraction or percentage how many test functions can be tested on a given coefficient. Both figures clearly indicate that the DHF hybrid comparable and outperformed the HHSFR CG coefficient.

Digital image processing plays an important role in medical sciences, biological engineering, and other science and engineering areas. Ibrahim et al. (2020) combined Solodov and Svaiter method with the Liu-Storey and Fletcher-Reeves conjugate gradient algorithm of Djordjevic unconstrained minimization problems to propose a hybrid conjugate gradient algorithm and extend the result to solve convex constrained nonlinear monotone equations. The global convergence established and applied to solve the $l_1$-norm regularized problems to restore sparse signal and image in compressive sensing. Numerical comparisons of the algorithm with some sparse signal reconstruction and image restoration in compressive sensing CG algorithms show that the proposed scheme is computationally more efficient and robust than the compared schemes. Ibrahim et al. (2020) utilized HLSFR Algorithm of Djordjevic (2019) in the restoration of one-dimensional sparse signal and image restoration using mean squared error (MSE). The performance of HLSFR won and proves to be more efficient in decoding sparse signals in compressive sensing by a lesser number of iterations, computing time, and lesser MSE by repeated experiment on 10 different noise samples. The HLSFR algorithm is similar to the HHSFR of Djordjevic (2018) and DHS algorithms here.

5. Conclusion

This paper has presented a new hybrid conjugate hybrid algorithm in which the CG parameter is computed as a convex combination of $\beta_k^{HS}$ and $\beta_k^{FR}$ from Dai-Liao conjugacy condition by employing an optimal choice of the modulating parameter $t$. Numerical computation adopts inexact line search, which is compared with HHSFR conjugate gradient coefficient proposed by Djordjevic. The method requires the first-order derivatives but overcomes the steepest descent method’s shortcoming of slow convergence and needs not to save or compute the second-order derivatives needed by the Newton method. Numerical results show that DHR coefficient outperforms the HHSFR scheme and suitable in compressed sensing. The algorithm converges globally using strong Wolfe conditions.
